01

Introduction

What problem it is solving ?

Problem :

Drivers in high-density areas lose an average of 20 minutes per trip searching for parking, leading to increased urban congestion, higher carbon emissions, and significant driver frustration due to a lack of real-time occupancy data.

Solution :

An automated, sensor-based solution designed to optimize urban mobility by real-time tracking of parking availability and providing seamless, touchless entry using Arduino-controlled hardware.

02

Social impact

Social impact

1. Environmental Sustainability (Reducing the Carbon Footprint)

By directing drivers straight to an available spot, your system significantly cuts down on idling time, reducing CO2 emissions and local air pollution.

2. Improved Quality of Life (Time Wealth)

Automating the process saves commuters an average of **15–20 minutes per trip**, allowing that time to be spent on productive work or family instead of being stuck in a car.

03

Use case

Useful at

- Airport
- Railway station
- Buildings and apartments
- Malls
- Corporate office
- Tech parks
